WICHE, the Western Interstate Commission for Higher Education, is a nonprofit regional organization. It helps the thirteen member states to work together to provide high-quality, cost-effective programs to meet the education and manpower needs of the West. Member states are Alaska, Arizona, California, Colorado, Hawaii, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming. Through its Information Clearinghouse, WICHE provides information to assist higher education and governmental policy makers in the West.

### **Foreword**

This report provides new information to the higher education community as it addresses the uncertainties surrounding enrollment planning during the next fifteen years or so. The "roller coaster" pattern in the numbers of high school graduates in all the states poses difficult problems for institutional and statewide planners as they seek rational, consistent policies to deal with recruitment, financing, capital improvements, curriculum development, and other critical issues. Although the high school graduate population represents only one segment of the total student body in our colleges and universities, it traditionally has been a principal source of enrollments. For this reason alone, reliable projections of demographic changes are significant data for those charged with responsibility for making decisions about the future of postsecondary education.

These projections of high school graduates have been updated, refined, and expanded from those developed in 1979 by William R. McConnell, a senior program director at the Western Interstate Commission for Higher Education (WICHE). He had almost completed work on the new projections at the time of his death in July 1983. This publication stands as a memorial to his many contributions to higher education planning and resource sharing, especially in the western region.

Norman Kaufman, director of WICHE's Information Clearinghouse, completed McConnell's work on the projections and prepared the narrative analysis. Louise Lawrence, administrative secretary in the Student Exchange Program, provided able assistance to both men in compiling the historical data and presenting the projections in various formats.

WICHE gratefully acknowledges the enthusiastic support of its co-publishers, the College Board and the Teachers Insurance and Annuity Association, and the additional financial assistance of the Lilly Endowment, Inc. They are among the increasing number of organizations to recognize the importance of identifying and understanding demographic patterns of high school graduates who continue to comprise the primary clientele of most colleges and universities.

WICHE also expresses its appreciation to the many individuals in state agencies and educational organizations who supplied data, answered questions, and commented on compilations and projections.

Boulder, Colorado December 1983 Phillip Sirotkin
Executive Director

### Introduction

The publication in 1979 of High School Graduates: Projections for the Fifty States provided the first comprehensive examination of the effects of declining birth rates and interstate migration on the numbers of public high school graduates in the fifty states. Although the higher education community was aware of the dimensions of the overall downturn in births, little was known, at the time, about how those effects would differ by state and region. The 1979 report provided valuable information for higher education planning because it translated demographic trends—births and interstate migration—into tangible measures directly related to college enrollments, namely, high school graduates. While many institutions serve large numbers of adults, returning students, and citizens of other countries, the curricular and recruitment efforts of an overwhelming number of institutions are oriented toward serving this traditional college-age clientele (i.e., 18-21 year olds).

This updated and expanded report provides new information for planners at colleges and universities, as well as for individuals concerned with state or local policies regarding higher education. The projections of high school graduates by state, region, or nation gives the planner or analyst a glimpse—albeit a fairly simple and quantitative one—of the trends that will affect student demand for a college education. In the past, it was relatively easy to extrapolate college enrollment rates and to apply them to successive cohorts of recent high school graduates (or the population aged 18-19 years) and to project college enrollments from the calculations. Today such projections must be more sophisticated, but they still rely on high school graduates as a major component. Thus, the projections presented in this report serve to focus attention both on policy concerns and on practical matters of student recruitment.

The projections in this report are based on the methods devised in the 1979 study. Data on grade-by-grade school enrollments and graduates were provided by the education agency in each state. The projections were made by the authors based on a careful analysis of the trends in each state. The methodology is described in a later section of the report. These projections cover both public and nonpublic graduates for twenty-two states and only public graduates for twenty-eight states and the District of Columbia.

Projections, including those presented here, are not predictions. They are, at root, contingent statements about the future. These statements are based on assumptions about net migration, grade-to-grade student progression, and retention from grade twelve through to graduation. Any changes in the assumptions about these factors will result in changes in the projected numbers of graduates. Likewise, differences between the projections and actual occurrences can be traced to differences between the assumptions made about the future and the actual experience. The reader should attempt to compare these projections with actual data on the numbers of high school graduates in future years.

The Western Interstate Commission for Higher Education will maintain a database of historical data and will attempt to issue occasional reports on or updates of the projections presented in this report. Copies of each state's historical data, projection table, and a line graph of the projections are available from WICHE. A compendium, which includes data on public and private enrollments (where they are available), is available for each of the four regions. Each regional compendium is available at a cost of \$15 (postpaid) and includes separate tables on all of the states in that region. Please specify the region or regions desired. A complete set of four compendiums is available for \$50. Data for individual states are available at a cost of \$2 per state. Complete copies of the data are available on diskette for an IBM Personal Computer and may be obtained by special arrangement.

2

# Projections of High School Graduates for the Fifty States and the District of Columbia

The projections of high school graduates presented here for each of the fifty states and the District of Columbia cover the period 1982 through 1999 or 2000 (depending on the availability of data on resident live births for 1982). The projections for twenty-two states are based on the combined numbers of graduates of public and nonpublic schools. The projections for the remaining twenty-eight states and the District of Columbia are for public high school graduates only, because reliable, consistent data on nonpublic enrollments and graduates were unavailable for those states. Table 1 lists the basis for the projections by state.

Readers attempting to compare the actual numbers of graduates projected in this study with the numbers projected in the earlier (1979) study should note the basis of the projections—public schools only or combined public and nonpublic schools—in the two studies. The authors attempted to obtain and use consistent and comparable data on public and nonpublic school enrollments and graduates, but found that the data on the latter were not available in a majority of states. Combined public and nonpublic data were used as a basis for projections when they were available because data on public graduates only do not always reflect changes in the birthrate, net migration, or shifts to nonpublic schools. For states in which data on public enrollments only are available, shifts to or from nonpublic schools are indistinguishable from migration.

### Overview

There are notable similarities among most of the states in some regions and notable contrasts among the various regions. For this reason, the discussion will proceed from general regional comparisons to more detailed state differences. With only a few exceptions noted later, the projections follow a common pattern:

- a decrease from the 1981 level to a low point in the 1984-87 period;
- an increase, in some cases very slight, to 1988 or 1989;
- a decrease to another low point in the 1990-94 period;
- for some states, an increase to the year 1999 or 2000, the last year of the projection; for others, an increase followed by a period of leveling off to the year 1999 or 2000.

These differences among states and regions in the period 1995-2000 result largely from differences in births between 1977 and 1982. Figures 1 and 2 show these patterns for the United States and for the four regions listed in Table 2. States are grouped into the Northeast, Northcentral, Southeast-Southcentral, and Western regions. These groupings follow the 1979 report, which revealed within-region similarities in the patterns of projected graduates. Nevertheless, there still are considerable within-region variations.

Table 1

Basis for Projections of High School Graduates

	Texas
	Utah
	Vermont
	Virginia
	Wyoming

Figures 3-6 show the pattern for each state in terms of the percentage change from the 1981 actual number of graduates. Each region's display also shows the nationwide pattern, which is based on the sum of the state totals, and the pattern for each region.

Every state and region shows a decrease in projected high school graduates between 1981 and some point in the 1984-87 period. For the District of Columbia, this point occurs in 1989. Most of the decreases are in the range of 10-20 percent and nearly one-fifth of the states are projected to experience declines greater than 20 percent. Several states in the West and Southeast-Southcentral regions are projected to experience declines of less than 10 percent in the 1984-87 period. In addition, these states will reach their low point earlier, in 1984 or 1985.

The projections for all states show a brief rebound in 1988 or 1989. In the West and Southeast-Southcentral regions, the number of high school graduates will approach the 1981 level. The 1988

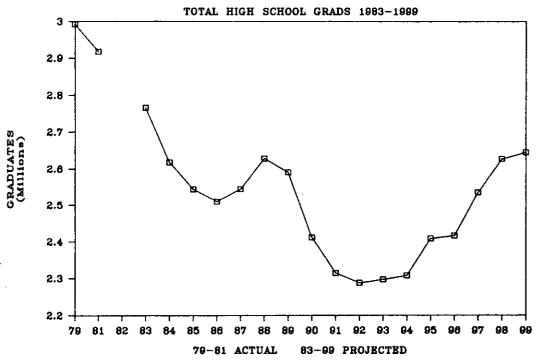

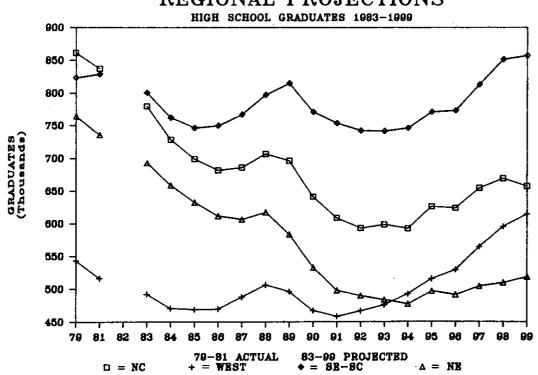

Figure 2

or 1989 projections for several states in both regions exceed the actual 1981 figures. Both the Northeast and Northcentral regions show weaker recoveries in the 1988-1989 period than the other two regions. The numbers of graduates in both regions are projected to fall 16 percent below the 1981 level, up slightly from their low points in 1986 and 1987. Again, there are noticeable differences among states, ranging from 3 percent below the 1981 total in Vermont to -42 percent in the District of Columbia. (See Figures 3-6.)

The period from 1990 to 1994 marks the low point for all four regions. The Northeast (Figure 3) reaches a 1994 low that is 35 percent below the 1981 level. The projected low point nationally comes in 1992, some 22 percent below the 1981 level. The range of low points in the Northeast region extends from -22 percent in Vermont in 1993 to -49 percent in the District of Columbia in 1994.

The Northcentral region (Figure 4) also reaches a low point in 1994, 29 percent below the number of graduates in 1981. Several states reach their lowest points earlier: Nebraska in 1990, South Dakota in 1991, and five states in 1992. Projected declines in the 1990-1994 period range from 21 percent below 1981 in Kansas to -37 percent in Michigan.

The low points in the West and the Southeast-Southcentral regions are projected to occur in 1991 and 1993, respectively. Both regions should experience lows that are about 11 percent below their 1981 levels. There will be considerable variations among the states in each of these two regions. With the exception of Texas, Oklahoma, and Florida, the projected lows for states in the Southeast-Southcentral region (Figure 5) are considerably below the lows reached in the 1984-87 period. In Texas, Oklahoma, and Florida, the downturns are less pronounced, and in Texas the 1991 low point is still 6 percent above 1981. A similar pattern emerges in the West (Figure 6), where Alaska, Utah, and Wyoming are projected to increase rather steadily their number of graduates above the 1981 level and where the low points of the early 1990's downturn in Idaho and Nevada will be higher than the low points in the 1984-87 period. The Western region's 1991 low point occurs the earliest of the four regions.

All four regions are projected to recover from their 1991-1994 low points, but at differing rates. By 1998, the Northcentral region is expected to have recovered to a level 20 percent below 1981, only to slip back to 22 percent below in 1999. Individual states show differing patterns, due to variations in their patterns of births in the period 1976 to 1982. In Kansas and North Dakota, for example, projected graduates for 2000 are, respectively, only 4 percent and 7 percent below their 1981 levels. In contrast, projections for Indiana in 2000 are 26 percent below 1981, up 2 percentage points from 1992.

Most of the states in the Northeast are projected to experience only a slight recovery through 1999. The region as a whole is projected to see a 1999 level of high school graduates that is 30 percent below the actual level in 1981. Only Vermont and the District of Columbia vary greatly from the pattern, with Vermont projected to experience a sharp increase in graduates and the federal district projected to post further declines.

The Southeast-Southcentral region is projected to increase from its 1993 low to a 1999 level that is 3 percent above 1981. However, only Florida, Louisiana, Oklahoma, and Texas are projected to exceed their respective 1981 numbers of graduates, while the remaining states will stay below their 1981 levels. West Virginia will continue its decline through the year 2000.

The West will see the sharpest upturn in the projected numbers of high school graduates. By 1999, the region is projected to exceed its 1981 level by 19 percent. Alaska, Arizona, Colorado, Idaho, Nevada, Utah, and Wyoming are projected to experience greater than average gains. Only Hawaii and Montana are projected to see their numbers of high school graduates remain below their 1981 levels.

These variations among states and regions, as well as within regions, are important to educational planning. Based on experience gained from the 1979 study, the overall trends and patterns depicted in the projections are expected to be sufficiently close to actual experience for many planning purposes although precise year-to-year percentage changes or absolute numbers of graduates will deviate from the projections.

This suggests that the policies and practices employed by states and by institutions to deal with the initial 1984-1987 downturn should vary in type as well as in degree of comprehensiveness.

In the absence of long-range projections, which establish basic trends, the somewhat cyclical pattern of ups and downs could be misinterpreted and lead to the selection of inappropriate policies or responses.

### Racial and Ethnic Minorities

One of the original aims of this study was to project separately the numbers of high school graduates in racial and ethnic minority groups. A lack of data in most states makes this type of analysis and projection impossible. A limited analysis of enrollments and grade progression in several states tends to corroborate the findings of other studies that reveal high rates of attrition for minorities in secondary schools. Efforts to improve these retention rates for minorities will undoubtedly affect the overall rates of graduation projected in this study.

### **Underlying Factors**

The principal factors underlying the patterns of projected high school graduates are the historical pattern of annual births in each state, interstate migration—past and projected for the future—and the rates of persistence of students in the later years of high school.

Births. The annual numbers of births in each state establish a basic pattern for the relative sizes of successive age groups in the population. The effects of this pattern on the population over time will be modified by other factors, especially migration. However, only very heavy net in-migration or out-migration over time is likely to alter significantly the basic pattern of increases or decreases in age-group sizes, which were established by the pattern of births.

Figure 7 shows the pattern of annual births from 1970 to 1981 for each of the four regions and for the nationwide sum of the regions. With 1970 as the base year of 1.000, the divergence of the regional lines is striking. Although all four regions experienced an upswing in the numbers of births from 1976 on, the upswing in the Western region began earlier (1972) and did not decline in 1980-1981, as did the other regions. This general upswing in births is reflected in the increases in the numbers of high school graduates after 1995.

Migration. Interstate migration affects the projections in two ways. As noted earlier, sustained net migration (either in or out) generally will be reflected in an increase or decrease in the annual number of births. These changes, in turn, are reflected in first-grade enrollments six years later. Heavy migration will also affect enrollments in the primary grades and is noted in the grade-to-grade progression data for grades two through six. For most states, the projections incorporate slight adjustments for migration but do not alter significantly the magnitude or direction of most state-by-state projections. For several states, however, the magnitude of net in-migration or out-migration appears to contribute to the net increase or decrease in the numbers of high school graduates. Illinois, Indiana, and Michigan, for example, appear to be so affected by net out-migration that their projections of high school graduates could not be projected from the pattern of births alone. Similarly, the following eight states—all in the West or South—appear to have experienced heavy net in-migration, which further influences their patterns of grade-to-grade enrollment changes: Alaska, Arizona, Florida, Georgia, Nevada, Oklahoma, Texas, and Wyoming.

Another way to infer the effects of migration is to compare enrollments in grades 2-5 for a given year with enrollments in grades 3-6 in the following year. If net migration were zero, one would expect enrollments in grades 3-6 to be only slightly lower than the previous year's total

for grades 2-5 (because of non-promotions and mortality, which is negligible). It is beyond the scope of the current project to quantify explicitly this inferred measure of migration, although the raw grade-by-grade enrollment data necessary to do so for each state are available from WICHE upon request.

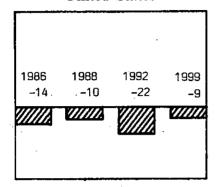

Persistence in High School. During the later high school years, there almost always will be a substantial decrease in the enrollment of a given cohort as it moves from tenth grade through to graduation from high school. In most states, the proportion of graduates to tenth graders is approximately 70-75 percent, largely attributed to dropouts once the age of compulsory attendance is passed. Any significant deviations from these historical ratios will cause the projections to vary from the actual numbers of graduates in future years.

West: Alaska, Arizona, California, Colorado, Hawaii, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, Wyoming (13).

Northeast: Connecticut, Delaware, District of Columbia, Maine, Maryland, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, Vermont (12).

Southeast-Southcentral: Alabama, Arkansas, Florida, Georgia, Kentucky, Louisiana, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, West Virginia (14).

Northcentral: Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, Wisconsin (12).

\*\*U.S. total is the sum of the four regional totals.

## Annual Projections of High School Graduates for Each State

Table 3 presents the annual number of graduates for each state: actual numbers reported by each state for the years 1975-76 through 1981-82 and projections for the years 1982-83 through 1999-2000. The designation under each state indicates whether the projections are for public high school graduates only or for graduates of public and nonpublic schools combined.

### Methodology

- 1. Building on the base of data acquired and developed in the course of completing its 1979 study, WICHE contacted education officials in each state to acquire data for the years 1978-79 through 1982-83.
- 2. The agency that compiles elementary and secondary enrollment statistics in each state was asked to provide uniform data on the following:
  - a. Fall enrollment for public and nonpublic schools.
  - b. Fall enrollment by racial and ethnic category for public and nonpublic schools.
  - c. Numbers of high school graduates by racial and ethnic category for public and nonpublic schools.
  - d. Any authoritative projections of high school graduates.

30

- 3. Useable data on nonpublic enrollments and graduates were received from twenty-two states, and the projections reported reflect these combined totals. Useable data on grade-by-grade enrollments for racial and ethnic groups were received from only four states, although another nine states did supply these data in some form.
- 4. The grade-by-grade enrollment data and numbers of high school graduates were entered into a microcomputer file and historical enrollments and grade-to-grade progression ratios were computed. Table 4 is an example of this worksheet for the state of Illinois. The grade-by-grade enrollment figures are shown by school year and grade. The numbers between each row and column entry are the ratios of enrollment in one grade to the enrollment in the next grade the following year (e.g., ratio of grade one in 1978-79 to grade two in 1979-80 in the example given is 0.965, and so on). The second and third columns list the number of resident live births six years prior to the school year listed. Column four depicts the ratio of first grade enrollments to births six years earlier. The farthest right column depicts the number of graduates in June of the school year.
- 5. Table 5 shows the projection table, which is produced when ratios are specified for each of the transitions for births to first grade enrollment, grade-to-grade enrollments from grades one through twelve, and grade twelve to the number of graduates.
- 6. The projection technique used is the grade-progression method. Using the historical data, the ratio of enrollment in first grade to number of resident live births six years earlier is calculated for each first grade group. The ratio of second-grade enrollment one year to first-grade enrollment the previous year is calculated for each second grade group. Similarly, a column of ratios is calculated for each move from grade to grade through twelfth grade. The ratio of high school graduates to enrollment in twelfth grade is calculated for each high school graduate group. These ratios reflect the combined effect of:

- a. migration—in the case of these statewide data, the net migration into or out of the state of individuals of the particular age or grade level involved.
- b. dropouts—especially in the later years of secondary school.
- c. nonpromotion—there is a tendency for a substantial proportion of first-grade students to be retained in first grade a second year, affecting both the ratio of first grade to births and the ratio of second grade to first grade. Lesser impact of this factor may occur at other grade levels.
- d. transfers from or to nonpublic schools—in these public school data, transfers from non-public schools affect the ratios, especially between sixth and seventh grade or between eighth and ninth grade, depending on the grade structure of the nonpublic schools. A general closing of nonpublic schools or a general shift to nonpublic schools would affect the ratios generally.
- e. shifting of students from regular grade groups to ungraded or special education groups cause special difficulties in interpreting the grade progression ratios.
- f. mortality (which is insignificant in the projections).
- 7. The key step in the projection process is the selection of: (1) the particular ratios to be used for each move from grade to grade; (2) the ratios to be used to translate the known birth figures into projected first-grade enrollments; and (3) the ratio between twelfth-grade enrollments and graduates. In the projections presented in this report, the selection of these ratios was done by case-by-case examination, rather than using a particular average from a specific period of the recent past. After careful study of the historical ratios, a judgment was made as to the appropriate ratio to use in each case.

In most cases, constant ratios selected for purposes of long-range projections were used. Variances in the short range between these projections and actual enrollments or graduates should be assessed carefully before concluding that the numbers projected for the longer range are invalid.
